

Data Mining (EECS 6412)

Data Preprocessing

Aijun An
Department of Electrical Engineering and Computer Science
York University

Process of Data Mining and KDD

Outline

- ▶ Why preprocess the data?
- ▶ Data integration
- ▶ Data cleaning
- ▶ Data transformation
- ▶ Data reduction
- ▶ Discretization

3

Why Data Preprocessing?

- ▶ Heterogeneous data – data integration
 - ▶ From various departments, in various forms
- ▶ Dirty data – data cleaning
 - ▶ Incomplete data: missing attribute values
 - ▶ e.g., occupation=""
 - ▶ Noisy data: containing errors
 - ▶ e.g., Salary="-10"
 - ▶ Discrepancies in codes or names
 - ▶ e.g., US=USA
- ▶ Data not in the right format – data transformation
 - ▶ Normalization, discretization, etc.
- ▶ A huge amount of data – data reduction
 - ▶ Speed up mining

No quality data, no quality mining results!

4

Major Tasks in Data Preprocessing

- ▶ **Data integration**
 - ▶ Integration of multiple databases or files
- ▶ **Data cleaning**
 - ▶ Fill in missing values, identify outliers and smooth out noisy data, and resolve discrepancies
- ▶ **Data transformation**
 - ▶ Feed right data to the mining algorithm
- ▶ **Data reduction**
 - ▶ Obtains reduced representation in volume but produces the same or similar analytical results
- ▶ **Data discretization**
 - ▶ Part of data reduction and data transformation but with particular importance, transform numerical data into symbolic (discrete) data

5

Data Integration

- ▶ **Data integration:**
 - ▶ combines data from multiple sources into a coherent store
- ▶ **Schema integration**
 - ▶ integrate metadata from different sources
 - ▶ *Entity identification problem*: identify real world entities from multiple data sources, e.g., A.cust-id \equiv B.cust-#
- ▶ **Detecting and resolving data value conflicts**
 - ▶ for the same real world entity, attribute values from different sources are different
 - ▶ possible reasons: different representations, different scales,
 - ▶ e.g., hotel price in different currencies, metric vs. British units
 - ▶ e.g., Age="42" Birthday="03/07/1997"
 - ▶ e.g., Was rating "1,2,3", now rating "A, B, C"

6

Data Cleaning

- ▶ Why is data dirty?
 - ▶ Incomplete data come from
 - ▶ human/hardware/software problems (e.g. equipment malfunction)
 - ▶ different consideration between the time when the data was collected and when it is analyzed.
 - ▶ certain data may not be considered important at the time of entry
 - ▶ Noisy data come from the process of
 - ▶ data collection
 - ▶ data entry
 - ▶ data transmission
- ▶ Data cleaning tasks
 - ▶ Fill in missing values
 - ▶ Identify outliers and smooth out noisy data

7

How to Handle Missing Values?

- ▶ Fill in the missing value manually: tedious + infeasible?
- ▶ Ignore the tuple containing missing values:

| Cust-id | Age | Gender | Income | Credit |
|---------|-----|--------|--------|--------|
| 1 | 36 | M | \$54K | good |
| 2 | 24 | M | \$20K | bad |
| 3 | 37 | M | \$50K | ? |
| 4 | 23 | F | \$30K | good |
| 5 | 55 | F | \$25K | good |
| 6 | 35 | ? | \$16K | bad |
| 7 | 33 | F | \$10K | bad |

 - ▶ usually done when class label is missing (assuming the task is classification)
 - ▶ not effective when missing values in attributes spread in many different tuples.
- ▶ Fill it in with a value “unknown”
 - ▶ patterns containing “unknown” is ugly

8

How to Handle Missing Values? (*Contd.*)

- ▶ Global estimation
 - ▶ the attribute mean/median for numeric attributes
 - ▶ the most probable value for symbolic (i.e. categorical) attributes
- ▶ Local estimation: smarter
 - ▶ the attribute mean/median for all the tuples belonging to the same class (for numeric attributes)
 - ▶ the most probable value within the same class (for symbolic attributes)

| Cust-id | Age | Gender | Income | Credit |
|---------|-----|--------|--------|--------|
| 1 | 36 | F | \$55K | good |
| 2 | 24 | ? | \$20K | bad |
| 3 | 37 | F | \$50K | good |
| 4 | 23 | F | \$30K | good |
| 5 | 55 | F | \$25K | good |
| 6 | 35 | M | ? | bad |
| 7 | 33 | M | \$10K | bad |

- ▶ Use inference-based prediction techniques, such as
 - ▶ Nearest-neighbor estimator, decision tree, regression, neural network, etc.
 - ▶ good method with overhead

9

Noisy Data

- ▶ Noise: random error or variance in a measured variable
- ▶ Incorrect attribute values may be due to
 - ▶ faulty data collection instruments
 - ▶ data entry problems
 - ▶ data transmission problems

10

How to Handle Noisy Data?

- ▶ Clustering
 - ▶ detect and remove outliers (An outlier is a value that does not follow the general pattern of the rest)
- ▶ Regression
 - ▶ smooth by fitting the data into regression functions
- ▶ Binning method:
 - ▶ first sort data and partition into bins
 - ▶ then one can smooth by bin means, smooth by bin median, smooth by bin boundaries, etc.
- ▶ Moving average
 - ▶ Use the arithmetic mean of neighborhood examples
- ▶ Combined computer and human inspection
 - ▶ detect suspicious values and check by human (e.g., deal with possible outliers)

11

Cluster Analysis

12

Regression

- ▶ Fit the data to a function.
- ▶ Data points too far away from the function are outliers.
- ▶ A *single linear regression*, for instance, finds the line to fit data with 2 variables so that one variable can predict the other.
- ▶ More variables can be involved in *multiple linear regression*.

13

Binning:

- ▶ **Equal-width** (distance) partitioning:
 - ▶ It divides the range of an attribute into N intervals of equal size: uniform grid
 - ▶ if A and B are the lowest and highest values of the attribute, the width of intervals will be: $W = (B - A)/N$.
 - ▶ The most straightforward
 - ▶ But outliers may dominate presentation
 - ▶ Skewed data is not handled well.
- ▶ **Equal-depth** (frequency) partitioning:
 - ▶ It divides the range into N intervals, each containing approximately the same number of values
 - ▶ Good data scaling; better handle skewed data

14

Equal-width Binning Methods for Smoothing Data

- * Sorted data for price (in dollars): 4, 8, 9, 15, 21, 21, 24, 25, 26, 28, 29, 34
- * Partition into (equi-width) bins: 3 intervals of equal size
 - Bin 1: 4, 8, 9
 - Bin 2: 15, 21, 21, 24
 - Bin 3: 25, 26, 28, 29, 34
- * Smoothing by bin means:
 - Bin 1: 7, 7, 7
 - Bin 2: 20, 20, 20, 20
 - Bin 3: 28, 28, 28, 28, 28
- * Smoothing by bin boundaries:
 - Bin 1: 4, 9, 9
 - Bin 2: 15, 24, 24, 24
 - Bin 3: 25, 25, 25, 25, 34

15

Equal-depth Binning Methods for Smoothing Data

- * Sorted data for price (in dollars): 4, 8, 9, 15, 21, 21, 24, 25, 26, 28, 29, 34 (12 points in total)
- * Partition into 3 (equi-depth) bins:
 - Bin 1: 4, 8, 9, 15
 - Bin 2: 21, 21, 24, 25
 - Bin 3: 26, 28, 29, 34
- * Smoothing by bin means:
 - Bin 1: 9, 9, 9, 9
 - Bin 2: 23, 23, 23, 23
 - Bin 3: 29, 29, 29, 29
- * Smoothing by bin boundaries:
 - Bin 1: 4, 4, 4, 15
 - Bin 2: 21, 21, 25, 25
 - Bin 3: 26, 26, 26, 34

16

Moving Average

- ▶ Use neighborhood values to smooth out noise
- ▶ Typically used for time-series data
 - ▶ Use series of arithmetic means over time
 - ▶ Result depends on choice of length L for computing mean.
- ▶ Can also be used on spatial data such as images

17

Moving Average Example

| Year | Sales | Moving Average |
|------|-------|----------------|
| 1994 | 2 | NA |
| 1995 | 5 | 3 |
| 1996 | 2 | 3 |
| 1997 | 2 | 3.67 |
| 1998 | 7 | 5 |
| 1999 | 6 | NA |

18

Outline

- ▶ Why preprocess the data?
- ▶ Data integration
- ▶ Data cleaning
- ▶ **Data transformation**
- ▶ Data reduction
- ▶ Discretization

19

Data Transformation

- ▶ Transform the data into appropriate form for mining
- ▶ Attribute/feature construction
 - ▶ New attributes constructed from the given ones
 - ▶ e.g., compute average sale amount using total sale amount divided by units sold.
- ▶ Normalization: scale attribute values to fall within a small, specified range
 - ▶ min-max normalization
 - ▶ z-score normalization
 - ▶ normalization by decimal scaling
- ▶ Discretization
 - ▶ Transform numeric attributes into symbolic attributes

20

Data Transformation: Normalization

► min-max normalization

$$v' = \frac{v - \min_A}{\max_A - \min_A} (\text{new_max}_A - \text{new_min}_A) + \text{new_min}_A$$

where \min_A and \max_A are the minimum and maximum values of attribute A , and $[\text{new_min}_A, \text{new_max}_A]$ is the new range

► Example: Attribute *income* has values

- \$12,000, \$20,000, \$25,000, \$30,000, \$45,000, \$60,000, \$73,600, \$98,000
- normalized into values in range [0, 1]:
0, 0.093, 0.151, 0.209, 0.384, 0.558, 0.716, 1

► Problems:

- “Out of bounds” error occurs if a future input case falls outside the original range for A
- A too big or too small value could be noise. If they are used as min or max value for normalization, the results are not reliable.

21

Data Transformation: Normalization (Contd.)

► z-score normalization

$$v' = \frac{v - \text{mean}_A}{s_A}$$

where mean_A is the mean of attribute A and s_A is the standard deviation of A (suppose values are : v_1, v_2, \dots, v_n):

$$s_A = \sqrt{\frac{1}{n-1} \sum_{i=1}^n (v_i - \text{mean}_A)^2}$$

► Example:

- The mean and standard deviation of the attribute *income* are 45,450 and 29735
- With z-score normalization, the values are transformed into:
-1.12, -0.86, -0.69, -0.52, -0.02, 0.49, 0.95, 1.77

► Advantages:

- useful when the actual min and max are unknown
- better deal with outliers than min-max normalization

22

Data Transformation: Normalization (Contd.)

- ▶ Normalization by decimal scaling

$$v_i' = \frac{v_i}{10^k}$$

where k is the smallest integer such that $\text{Max}(|v_i'|) \leq 1$

- ▶ Example:

- ▶ Suppose the recorded values of A range from -986 to 97
- ▶ The maximum absolute value of A is 986.
- ▶ Then $k = 3$
- ▶ -986 is normalized to -0.986 and 97 is normalized to 0.097

23

Outline

- ▶ Why preprocess the data?
- ▶ Data integration
- ▶ Data cleaning
- ▶ Data transformation
- ▶ Data reduction
- ▶ Discretization

24

Data Reduction

- ▶ What is data reduction?
 - ▶ A preprocessing step before applying learning or mining techniques to the data
 - ▶ Purpose: reduce the size of data.
- ▶ Why data reduction?
 - ▶ A data set may be too large for a learning program. The dimensions exceed the processing capacity of the program.
 - ▶ The expected time for inducing a solution may be too long. Trade off accuracy for speed-up.
 - ▶ Sometimes, better answers are found by using a reduced subset of the available data. Too large data may cause the program to fit too many exceptions.

25

Data Reduction Operations

- ▶ Standard data form

| <i>Case/Example</i> | <i>feature₁</i> | <i>...</i> | <i>feature_k</i> | <i>Class</i> |
|---------------------|----------------------------|------------|----------------------------|--------------|
| e_1 | $V_{1,1}$ | \dots | $V_{1,k}$ | c_1 |
| \dots | \dots | \dots | \dots | \dots |
| e_i | $V_{i,1}$ | \dots | $V_{i,k}$ | c_i |
| \dots | \dots | \dots | \dots | \dots |
| e_n | $V_{n,1}$ | \dots | $V_{n,k}$ | c_n |

- ▶ Data reduction operations
 - ▶ Feature reduction (reduce the number of columns)
 - ▶ Case reduction (reduce the number of rows)
 - ▶ Value reduction (reduce the number of distinct values in a column)

26

Types of Attributes (Features)

- ▶ Three types of attributes:
 - ▶ Nominal (symbolic, categorical) — values from an unordered set
 - ▶ Eg: {red, yellow, blue, ...}
 - ▶ Ordinal — values from an ordered set
 - ▶ Eg: {low, medium, high}
 - ▶ Continuous — real numbers
 - ▶ Eg: {-9.8, 3.9, 8.7, 19.1}
- ▶ Next: feature selection for classification tasks.

27

Feature Selection

- ▶ Objective
 - ▶ Find a subset of features with predictive performance comparable to the full set of features.
 - ▶ An optimal subset selection

- ▶ A *practical objective* is to remove clearly extraneous features - leaving the table reduced to manageable dimensions - not necessarily to select the optimal subset.

28

Feature Selection Methods

- ▶ Filter Methods: select a subset of original features.
 - ▶ Feature Selection from Means and Variances (\checkmark)
 - ▶ Feature Selection by Mutual Information (\checkmark)
 - ▶ Feature Selection by Decision Trees (\checkmark)
 - ▶ Feature Selection by Rough Sets, etc.
- ▶ Merger Methods: merge features, resulting in a new set of fewer columns with new values.
 - ▶ Principal component analysis (PCA)
- ▶ Wrapper Methods: feature selection is being “wrapper around” a learning algorithm.
 - ▶ This is the optimal method in the last slide.
 - ▶ Running time is long; infeasible in practice if there are many features.

29
